

# Resolve System Capacity Issue by Redirecting Flow Traffic to New Network

- 1 Determine system loading from NWSA by analyzing wastewater user data logs. Determine combined flows from NWSA and EWSA1.
- 2 Analyze pump curves at PS1 to determine if there is adequate capacity to accept and redirect combined flows to proposed PSX.
- 3 Analyze flow data from PS2 SCADA system to determine remaining capacity in the TFM; if there is adequate capacity, the TFM can accept combined flows from PSX.
- 4 Collect discharge pressure data at PS2 from SCADA system to set baseline for Step 5.
- 5 Calculate theoretical pressure conditions at PCP in the TFM using Hazen-Williams and Darcy Weisbach equations.
- 6 Design PSX (see page 2):
  - a Size the pumps to (1) handle all flow loading conditions from PS1 as determined in Step 1, and (2) have adequate power to overcome theoretical pressure at PCP in the TFM as determined in Step 5.
  - b Implement variable frequency drives (VFDs) in PSX to scale discharge flow rates into the TFM to maintain ideal system conditions (ie. pipe velocities and pressures).
- 7 Abandon connection to FMA.
- 8 Connect Network A to Network B by establishing connections between NWSA, PS1, PSX, and the TFM.

# Calculations Required for Step 6a, Designing Pump Station 'PSX'

## 1. Calculations to Determine Suction & Discharge Heads (Energy) in Pump

## 2. Graph Design Point
